Suppose I have a function like: `def main(): return f('%s/file.txt') %('/')` This function takes any single character and returns a string containing that character, preceded by the root directory. For example, if the input were '/' (the root directory), the output would be 'file.txt'. So, if the input is 'a' (any character), the output would be '/a/file.txt'. I would like to be able to do this recursively, so that if the input is 'file.txt', the output would be 'file.txt'. Is this possible? The closest I can get is: `def main(): return f('%s/file.txt') %('/')` `def f(name): if name == 'file.txt': return name else: return f(name) + '/'` but, of course, this doesn't work. A: You are close. You need to return the call to f. I'll give you an example of this to make it clear. `def my_main(): return '/foo/bar.txt'` `def my_f(name): if name == 'bar.txt': return name else:`
