So as we now have the API's, libraries and documents in the right place, we can now write our first script. We are going to start with a basic script where we will run through how to use the API's. So Open up the script editor and create a new script with a name of "Start". In our script we need two things. Firstly we need to get the information that we need to use from the API. So we need to create a variable "url", and then set it to " We can set the URL to that specific user. So now we have the URL. The next thing we need to do is get the info from that API. To do this we need to

use the "GET" method and we can retrieve info from "data". The next thing we need to do is access the "data" and get the json response. The next thing we need to do is get the "name" of the application. To do this we need to use the "get" method and this gives us the user information. So now we have the user, and the application name. To create a application you need to use the "

The memory problem is called "Out of memory error", which is an often ignored programming error by beginner programmers. However, it is more or less important to have a good memory when programming. Get memories basics In computer science, there are three parts of memory, and they are defined as follows. RAM is the memory cache, where the data is stored temporarily before they are processed. Besides that, there is a DRAM module, where information is stored permanently, while the working memory is the temporary storage, which is where the instructions are stored temporarily. There are two main categories for RAM, and one is the fixed part, and the other is the volatile memory. Fixed memory is non-volatile memory, and so it is used when you want to save your data, and it's usually slower than the volatile memory. Traces of memory Memory is "traces" of the code. Each instruction accesses a memory cell, and so if there is no RAM, there will be no instructions. So it is important to know where is the memory. The "Hex" in the error means an address. For example, the number in front of 16 would be the address at which the instruction was executed. Out of memory errors A hardware error is seen when something goes wrong with the RAM. However, there can be several reason for the error. Read more: Out of Memory Algorithm There are different consequences when you're dealing with an out of memory error. But the most common errors are related to the code creating error, which will lead to an "out of memory" error. With the help of the following parts, you can fix this error and save the needed memories. Clear all caches After a new RAM module is installed, it takes some time before the RAM module is functional. This is a common error. To start operating the new module, you must clear all cache in the CPU. Rerun the program You are sure that a new RAM module is installed and the problem is fixed. But
